Abstract
In the present work, the temperature dependence of the scalar meson parameters is investigated in the framework of thermal QCD sum rules. We calculate the $\sigma$-pole and the non-resonant two-pion continuum contributions to the spectral density. Taking into account additional operators appearing at finite temperature, the thermal QCD sum rules are derived. The temperature dependence of the shifts in the mass and leptonic decay constant of the scalar $\sigma(600)$ meson is calculated.

1. Introduction

The QCD sum rules method [1], proposed about three decades ago, is one of the powerful methods for investigating the properties of hadrons. This method has been extensively used as an efficient tool to study the masses, decay form factors and so on [2]. In recent years there has been increasing interest in the modification of hadronic properties at finite temperature in order to understand the results of the heavy-ion collision experiments.

The QCD sum rules method is extended to the finite-temperature in [3] and finite-temperature sum rules have several new features. One of them is the interaction of the current with the particles of the medium. This effect requires modifying hadron spectral function. The other novel feature is the breakdown of Lorentz invariance by the choice of reference frame [4, 6]. Due to the residual $O(3)$ symmetry more operators with the same dimension appear in the operator product expansion (OPE) at finite temperature compared to those at zero temperature. Taking into account both complications, the investigation of OPE for the thermal correlator of the two vector currents, and the thermal QCD sum rules for vector mesons have been realized in [7, 8], respectively. Also, nuclear medium modifications of meson parameters are widely discussed in the literature [9, 10].

At high temperature restoration of symmetries and deconfinement are expected. In this connection the study of scalar mesons at finite temperature receives special attention, since the origin of mass of these mesons is associated with chiral symmetry breaking. The study of temperature dependence of physical parameters of these mesons can give us hints of a possible
restoration of symmetries. Restoration of chiral symmetry breaking is related to the phase transition of hadrons to the quark–gluon plasma.

In the present work, we investigate the properties of the scalar $\sigma$ meson in the framework of thermal QCD sum rules. The basic idea of thermal QCD sum rules is to get information about temperature dependence of hadron parameters, studying the same correlator, both at high temperature where the quark–gluon plasma is expected and at low temperature, where the hadronic phase is dominated. Note that the nature of light scalar mesons is still an open problem and is the subject of intensive and continuous theoretical [11] and experimental investigations [12]. Several different pictures for the scalar mesons have been proposed: conventional $q\bar{q}$ states [13], glueballs, hybrid states, molecule states [14], four quark states [15, 16], etc. Can we get any new information about the nature of the scalar mesons from the thermal QCD analysis? The present work is addressed to the investigation of this problem.

This paper is organized as follows. In section 2, we derive the thermal QCD sum rules for the scalar $\sigma$ meson. In section 3 we present our numerical calculations. This section also contains discussion and our conclusion.

2. Thermal QCD sum rules for scalar sigma mesons

In this section we construct the thermal sum rules for the scalar $\sigma(600)$ meson. For this purpose we consider the thermal average of correlation function

$$T(q) = i \int d^4x \; e^{i q \cdot x} \langle T(J(x)J(0))\rangle,$$

(1)

where $J(x) = \frac{1}{\sqrt{2}}(\bar{u}u + \bar{d}d)$ is the interpolating current with the $\sigma$ meson quantum numbers. The thermal average of any operator is determined by the following expression,

$$\langle O \rangle = \text{Tr} \; e^{-\beta H} \; O / \text{Tr} \; e^{-\beta H},$$

(2)

where $H$ is the QCD Hamiltonian, and $\beta = 1/T$ stands for the inverse of the temperature $T$ and traces are carried out over any complete set of states.

The fundamental assumption of Wilson expansion is that the product of operators at different points can be expanded as the sum of local operators with the momentum-dependent coefficients in the form

$$T(q) = \sum_n C_n(q^2) \langle O_n \rangle,$$

(3)

where $C_n(q^2)$ are called Wilson coefficients, and $O_n$ are a set of local operators. In this expansion, the operators are ordered according to their dimension $d$. The lowest dimension operator with $d = 0$ is the unit operator associated with the perturbative contribution. In the vacuum sum rules operators with dimensions $d = 3$ and $d = 4$ composed of quark and gluon fields are the quark condensate $\langle \bar{\psi}\psi \rangle$ and the gluon condensate $\langle G_{\mu\nu}^a G^{a\mu\nu} \rangle$, respectively. At finite temperature Lorentz invariance is broken by the choice of a preferred frame of reference, and therefore new operators appear in the Wilson expansion. In order to restore Lorentz invariance in thermal field theory, the four-vector velocity of the medium $u^\mu$ is introduced. Using the four-vector velocity and quark/gluon fields, we can construct a new set of low-dimension operators $\langle u \Theta^I u \rangle$ and $\langle u \Theta^S u \rangle$ with dimension $d = 4$, where $\Theta^I_{\mu\nu}$ and $\Theta^S_{\mu\nu}$ are fermionic and gluonic parts of energy–momentum tensor $\Theta^\mu_{\mu\nu}$, respectively. So, we can write the thermal correlation function in terms of operators up to dimension four:

$$T(q) = C_1 I + C_2 \langle \bar{\psi}\psi \rangle + C_3 \langle G_{\mu\nu}^a G^{a\mu\nu} \rangle + C_4 \langle u \Theta^I u \rangle + C_5 \langle u \Theta^S u \rangle.$$

(4)
The Wilson coefficients in equation (4) are calculated in [17], and the renormalization group improved expression of OPE leads to the following result:

\[
T(Q) = \frac{3}{8\pi^2} Q^2 \left( \gamma - \ln \frac{4\pi}{Q^2} \right) + \frac{3}{Q^2} m^2 \langle \bar{\psi} \psi \rangle + \frac{g^2}{32\pi^2 Q^2} G^{a\mu\nu} G_{a\mu\nu}
\]

\[
+ \frac{4}{16 + 3n_f} \left( \frac{4(u - Q)^2}{Q^2} + \frac{1}{Q^2} \right) \left[ \langle u\Theta u \rangle + \lambda(Q^2) \left( \frac{16}{3} \langle u\Theta' u \rangle - \langle u\Theta^u u \rangle \right) \right],
\]

(5)

where \( Q \) is the Euclidean momentum, \( \lambda(Q^2) = [\alpha_s(\mu^2)/\alpha_s(Q^2)]^{-\delta/b} \) and \( \Theta_{\mu\nu} = n_f \Theta_{\mu\nu}^I + \Theta_{\mu\nu}^g \). At the one-loop level the constants \( \delta \) and \( b \) are given by

\[
\delta = \frac{\gamma}{2} \left( \frac{16}{\pi} + n_f \right) \quad \text{and} \quad b = 11 - \frac{3}{2} n_f,
\]

(6)

where \( n_f \) is the quark flavour number. The spectral representation for the correlation function in \( q_0 \) at fixed \( |\mathbf{q}| \) can be written as [8]

\[
T(q_0, |\mathbf{q}|) = \int_0^\infty d|\mathbf{q}|^2 \frac{N(q_0, |\mathbf{q}|)}{q_0^2 + Q_0^2} + \text{subtraction terms},
\]

(7)

where

\[
N(q_0, |\mathbf{q}|) = \frac{1}{\pi} \text{Im} T(q_0, |\mathbf{q}|) \tanh(\beta q_0/2) \quad \text{and} \quad Q_0^2 = -q_0^2.
\]

(8)

Note that the subtraction terms are removed by the Borel transformation. For this reason in further discussion we omit these terms. Equating spectral representation and OPE and performing Borel transformations with respect to \( Q_0^2 \) from both sides of equation (7), we obtain the QCD sum rules

\[
\int_0^\infty d|\mathbf{q}|^2 \ e^{-|\mathbf{q}|^2/M^2} N(q_0, |\mathbf{q}|) = e^{-q_0^2/M^2} \left[ \frac{3M^4}{8\pi^2} + \langle O_1 \rangle + \left( 1 - \frac{4q_0^2}{3M^2} \right) \langle O_2 \rangle \right],
\]

(9)

where \( M \) is the Borel parameter, \( \langle O_1 \rangle \) and \( \langle O_2 \rangle \) are the non-perturbative contributions of higher dimensional operators,

\[
\langle O_1 \rangle = 3m \langle \bar{\psi} \psi \rangle + \frac{g^2}{32\pi^2} G_{a\mu\nu} G^{a\mu\nu},
\]

(10)

\[
\langle O_2 \rangle = -\frac{12}{16 + 3n_f} \left[ \langle u\Theta u \rangle + \lambda \langle M^2 \rangle \left( \frac{16}{3} \langle u\Theta' u \rangle - \langle u\Theta^u u \rangle \right) \right].
\]

(11)

Now we consider the phenomenological part of the correlation function. We shall work below the critical temperature, where the physical spectrum is saturated by hadrons. In this case, similar to the vacuum QCD sum rules, the dominant contribution to the spectral density comes from \( \sigma \) mesons. We also calculate the contribution of the non-resonant two-pion continuum.

Let us calculate the \( \sigma \)-pole contribution to the correlator. The leptonic decay constant \( \lambda_\sigma \) of the \( \sigma \)-meson is given by \( \langle 0 | J(0) | \sigma \rangle = m_\sigma \lambda_\sigma \), where \( m_\sigma \) is the \( \sigma \)-meson mass. In thermal field theory, the parameters \( m_\sigma \) and \( \lambda_\sigma \) must be replaced by their temperature-dependent values. The vacuum value of the leptonic decay constant is obtained from two point QCD sum rules and \( \lambda_\sigma = 200 \text{ MeV} \) [18]. The absorptive part of the correlation function is calculated by using the following field-current identity,

\[
J(x) = m_\sigma \lambda_\sigma \sigma(x),
\]

(12)

and the \( \sigma \)-meson contribution to the thermal correlator can be written as

\[
T(q) = ig_\sigma^2 \lambda_\sigma^2 D_{t1}^\sigma(q).
\]

(13)
Here $D_{11}^\sigma(q) = \int d^4x \, e^{i q \cdot x} \langle T(\sigma(x)\sigma(0)) \rangle$ is the time-ordered product of two $\sigma$-meson fields (11-component of the finite-temperature scalar field propagator with mass $m_\sigma$ in the real time formalism) and has the following form \cite{19, 20},

$$D_{11}^\sigma(q) = \frac{i}{q^2 - m_\sigma^2 + i\varepsilon} + 2\pi n(\omega_q) \delta(q^2 - m_\sigma^2),$$  \hspace{1cm} (14)

where $n(\omega_q)$ is the Bose distribution function, $n(\omega_q) = [\exp(\beta\omega_q) - 1]^{-1}$ and $\omega_q = \sqrt{q^2 + m_\sigma^2}$. The imaginary part of the correlation function can be simply evaluated using the formula

$$\frac{i}{\pi\varepsilon} = \pi \delta(x) + iP(\frac{1}{2}),$$

which leads to

$$\text{Im} \, T(q) = \pi m_\sigma^2 \lambda_\sigma^2 (2n(\omega_q) + 1) \delta(q^2 - m_\sigma^2).$$ \hspace{1cm} (15)

Here we would like to make the following cautionary note. The scalar mesons have large decay widths and therefore width effects should be considered. In this direction the first attempt was made in \cite{21}. Using the Gaussian distribution for the phenomenological spectral density instead of the usual delta function in \cite{16}, it is obtained that the masses of the scalar mesons do not change significantly. For this reason, as a first approximation one can work with the delta function distribution; however the question of finite decay width is important and deserves more careful consideration. With the help of $\delta$-function we obtain the following result for the $\sigma$-pole contribution to the spectral function:

$$N(q) = m_\sigma^2 \lambda_\sigma^2 \delta(q^2 - m_\sigma^2).$$ \hspace{1cm} (16)

In order to calculate the dependence of $m_\sigma$ and $\lambda_\sigma$ on temperature, we consider appropriate loop diagrams. Let us calculate the $\pi\pi$-contribution to the amplitudes, which describes the interaction of the current with the particles in the medium. This contribution to the correlation function can be written as

$$T(q) = ig_\pi^2 \int \frac{d^4k}{(2\pi)^4} D_{11}^\pi(k) D_{11}^\sigma(k - q).$$ \hspace{1cm} (17)

where $D_{11}^\pi(k)$ is the 11-component of the finite-temperature propagator for pions and $g_\pi = 2, 0$ GeV \cite{22, 23}. The integration over $k_0$ in equation (17) can be evaluated using the residue theorem. After integration and some simplifications for the imaginary part of the correlation function we obtain

$$\text{Im} \, T(q) = \pi g_\pi^2 \int \frac{dk}{(2\pi)^4} \frac{1}{4\omega_1\omega_2} ((1 + n_1)(1 + n_2) + n_1n_2) (\delta(q_0 - \omega_1 - \omega_2)$$

$$\text{Im} \, T(q) = \pi g_\pi^2 \int \frac{dk}{(2\pi)^4} \frac{1}{4\omega_1\omega_2} ((1 + n_1)(1 + n_2) + n_1n_2) (\delta(q_0 - \omega_1 - \omega_2)$$

$$+ \delta(q_0 + \omega_1 + \omega_2)) + ((1 + n_1)n_2 + (1 + n_2)n_1)(\delta(q_0 - \omega_1 + \omega_2)$$

$$+ \delta(q_0 + \omega_1 - \omega_2)),$$ \hspace{1cm} (18)

where,

$$n_1 = n(\omega_1), \quad n_2 = n(\omega_2), \quad \omega_1 = \sqrt{k^2 + m_\pi^2}, \quad \omega_2 = \sqrt{(k - q)^2 + m_\pi^2}. $$ \hspace{1cm} (19)

At the values $q_0 = \omega_1 + \omega_2$ and $q_0 = \omega_1 - \omega_2$ the terms involving the density distributions can be written as

$$[(1 + n_1)(1 + n_2) + n_1n_2] \tanh \left( \frac{\beta q_0}{2} \right) = (n_1 + n_2 + 1),$$ \hspace{1cm} (20)

$$[(1 + n_1)n_2 + (1 + n_2)n_1] \tanh \left( \frac{\beta q_0}{2} \right) = (n_2 - n_1),$$ \hspace{1cm} (21)

respectively. As can be seen, the delta function $\delta(q_0 - \omega_1 - \omega_2)$ in equation (18) gives the first branch cut, $q^2 \geq 4m_\pi^2$, which coincides with the zero-temperature cut that describes the
standard threshold for particle decays. On the other hand, the delta function \( \delta(q_0 - \omega_1 + \omega_2) \) in equation (18) shows that an additional branch cut arises at finite temperature, \( q^2 \leq 0 \), which corresponds to particle absorption from the medium. Therefore, the delta functions \( \delta(q_0 - \omega_1 - \omega_2) \) and \( \delta(q_0 - \omega_1 + \omega_2) \) in equation (18) contribute to the regions \( q^2 \geq 4m^2_\pi \) and \( q^2 \leq 0 \), respectively. Taking into account both contributions, the spectral function can be written as

\[
N(q) = g^2 \int \frac{k^2 \sin \theta \, dk \, d\theta}{(2\pi)^2} (n_1 + n_2 + 1) \theta[q^2 - 4m^2_\pi] + (n_2 - n_1) \theta(-q^2)
\]

\[
\times \delta(q^2 - 2q_0\omega_1 + 2|\mathbf{k}|\mathbf{q} \cos \theta).
\]

(22)

The integration over the angle \( \theta \) in equation (22) can be evaluated using the constraint \( |\cos \theta_{\mathbf{k}, \mathbf{q}}| \leq 1 \), which leads to the following inequality:

\[
\frac{|q^2 - 2q_0\omega_1|}{2|\mathbf{k}|\mathbf{q}} \leq 1.
\]

(23)

The solution of this inequality at values \( q^2 \geq 4m^2_\pi \) gives us the integration range of \( \omega_1 \) as \( \omega_- \leq \omega \leq \omega_+ \), where

\[
\omega_\pm = \frac{1}{2}(q_0 \pm |\mathbf{q}|v),
\]

(24)

\[
v(q^2) = \sqrt{1 - 4m^2_\pi/q^2}.
\]

(25)

At \( q^2 \leq 0 \) the region of variation of \( \omega_1 \) must be \( \omega_- \leq \omega \leq \omega_+ < \infty \). Finally, the thermal spectral function can be written as

\[
N(q) = \frac{g^2}{2|\mathbf{q}|} \int_{\omega_-}^{\omega_+} d\omega_1 (n_1 + n_2 + 1) \theta[q^2 - 4m^2_\pi] + \frac{g^2}{2|\mathbf{q}|} \int_{\omega_-}^{\omega_+} d\omega_1 \frac{\omega_1}{(2\pi)^2} (n_2 - n_1) \theta(-q^2).
\]

(26)

Changing the variable \( \omega_1 \) to \( x \) given by \( \omega_1 = \frac{1}{2}(q_0 + |\mathbf{q}|x) \), we finally get the two-pion contribution to the spectral function as

\[
N(q) \equiv N_1(q) = \frac{g^2}{8\pi^2} v(q^2) + \frac{g^2}{8\pi^2} \int_{-v}^{v} dx \left[ n\left(\frac{1}{2}(q_0 + |\mathbf{q}|x)\right) - n\left(\frac{1}{2}(q_0 - |\mathbf{q}|x)\right)\right], \quad q^2 \geq 4m^2
\]

(27)

\[
N(q) \equiv N_2(q) = \frac{g^2}{16\pi^2} \int_{-v}^{v} dx \left[ n\left(\frac{1}{2}(q_0 + |\mathbf{q}|x + q_0)\right) - n\left(\frac{1}{2}(q_0 - |\mathbf{q}|x + q_0)\right)\right], \quad q^2 \leq 0
\]

(28)

The QCD sum rules are obtained by equating the theoretical and phenomenological parts of the correlation function. Taking into account expressions, equation (27) and equation (28), in equation (9) we get

\[
m^2_v(T)\lambda^2_v(T) e^{-m^2_v(T)/M^2} + \frac{g^2}{8\pi^2} e^{q^2/M^2} \int_{4m^2_\pi + q^2}^{\infty} dq_0^2 e^{-q_0^2/M^2} v(q^2)
\]

\[
+ e^{q^2/M^2} \left( \int_{4m^2_\pi + q^2}^{\infty} dq_0^2 e^{-q_0^2/M^2} N_1(q_0, |\mathbf{q}|) + \int_{0}^{q^2} dq_0^2 e^{-q_0^2/M^2} N_2(q_0, |\mathbf{q}|) \right)
\]

\[
= \frac{3M^4}{8\pi^2} + \langle O_1 \rangle + \left( 1 - \frac{4q^2}{3M^2} \right) \langle O_2 \rangle.
\]

(29)
As the temperature approaches zero, the two terms in the bracket go to zero and the thermal average of the operators on the right becomes the expectation values, recovering the vacuum sum rules [18]. In the limit \(|q| \to 0\), the sum rule (29) simplifies considerably. Finally we obtain that

\[
m^2_\sigma(T)\lambda^2_\sigma(T) \exp\left(-m^2_\sigma(T)/M^2\right) + I_0(M^2) + I_1(M^2) = \frac{3M^4}{8\pi^2} + \langle O \rangle,
\]

(30)

where

\[
I_0(M^2) = \frac{g^2_\sigma}{8\pi^2} \int_{4m^2_\sigma}^\infty ds \, v(s) \exp(-s/M^2),
\]

(31)

\[
I_1(M^2) = \frac{g^2_\sigma}{4\pi^2} \int_{4m^2_\sigma}^\infty ds \, v(s)n(\sqrt{s}/2) \exp(-s/M^2),
\]

(32)

\[
\langle O \rangle = \langle O_1 \rangle + \langle O_2 \rangle,
\]

(33)

3. Numerical analysis of the shifts in mass and leptonic decay constant

In this section, we present our results for the temperature dependence of the shifts in the \(\sigma\)-meson mass and leptonic decay constant. By derivativing with respect to \(1/M^2\) from both sides of the sum rules (30), and making some transformations we obtain

\[
m^2_\sigma(T)\lambda^2_\sigma(T) \exp\left(-m^2_\sigma(T)/M^2\right) - J_1(M^2) + \eta(\langle O \rangle)
\]

\[
\lambda^2_\sigma(T) = \lambda^2_\sigma \left[ m^2_\sigma \lambda^2_\sigma + \left( \frac{1}{M^2} - \frac{1}{m^2_\sigma} \right) [J_1(M^2) - \eta(\langle O \rangle) + m^2_\sigma(\langle O \rangle - I_1(M^2))] \exp\left(\frac{m^2_\sigma}{M^2}\right) \right],
\]

(34)

where the bar on the operators means subtractions of their vacuum expectation values and

\[
\eta(M^2) = \frac{\delta M^2}{b \ln(M^2/\Lambda^2)},
\]

(36)

\[
J_1(M^2) = \frac{g^2_\sigma}{4\pi^2} \int_{4m^2_\sigma}^\infty ds \, v(s)n(\sqrt{s}/2) \exp(-s/M^2),
\]

(37)

\[
\langle O \rangle = -\frac{1}{16 + 3n_f} \lambda(M^2) \left( \frac{16}{3} \langle u\Theta^{D}u \rangle - \langle u\Theta^{T}u \rangle \right).
\]

(38)

For the numerical analysis, let us list the thermal average of operators contributing to the QCD sum rules. The temperature dependence of the quark condensate is known from the chiral perturbation theory [24, 25]

\[
\langle \bar{\psi}\psi \rangle = \langle 0 | \bar{\psi}\psi | 0 \rangle \left[ 1 - \frac{n_f^2 - 1}{n_f} - \frac{T^2}{12F^2} + O(T^4) \right],
\]

(39)

where \(n_f\) is the number of quark flavours and \(F = 0.088\ \text{GeV}\). The low-temperature expansion of the gluon condensate has been studied in the article [26, 27],

\[
\frac{g^2}{4\pi^2} \langle G_{\mu\nu}^a G^{a\mu\nu} \rangle = -\frac{8}{9} \left( \langle \Theta^\mu \rangle + \sum_f m_f \langle \bar{\psi}\psi \rangle \right),
\]

(40)
where the trace of the total energy–momentum tensor $\Theta^\mu_\mu$ is given by $\langle \Theta^\mu_\mu \rangle = \langle \Theta \rangle - 3 p$, and for two massless quarks in the low-temperature chiral perturbation limit the trace has the following form [24]:

$$\langle \Theta^\mu_\mu \rangle = \frac{\pi^2}{270} \frac{T^8}{F_\pi^4} \ln \frac{\Lambda_p}{T} + O(T^{10}). \tag{41}$$

Here $\langle \Theta \rangle$ is the total energy density and $p$ is the pressure, whose expressions are known in the low-temperature region [25]. The pion decay constant has the value of $F_\pi = 0.093$ GeV and the logarithmic scale factor is $\Lambda_p = 0.275$ GeV. We also use the fact that the quark and gluon energy densities at finite temperature can be expressed as $n_f \langle \Theta^j \rangle = \langle \Theta^g \rangle = \frac{1}{2} \langle \Theta \rangle$, which agrees with both the naive counting of the degrees of freedom and empirical studies of the pion structure functions [4, 8]. For the numerical evolution of the above sum rule, we use the values $m \langle \bar{\psi} \psi \rangle = -0.82 \times 10^{-4}$ GeV$^4$, $\Lambda = 0.230$ GeV and $m_\sigma = 0.6$ GeV. We study the dependence of $\sigma$-meson mass and leptonic decay constant on $M^2$, when $M^2$ changes between
0.9 GeV$^2$ and 1.4 GeV$^2$. This region of $M^2$ is obtained from the mass sum rule analysis of the $\sigma$ meson [18]. The shifts in the $\sigma$-meson mass and leptonic decay constant as a function of temperature for different values of $M^2$ are shown in figures 1 and 2, respectively. As seen, the results for $\Delta m_{\sigma}$ are stable for temperatures up to 120 MeV. At high temperatures the results for $\Delta m_{\sigma}$ become unstable and the contributions of higher dimensional operators become important here, whose inclusions might restore the stability in $M^2$ to higher temperatures. The results for $\Delta \lambda_{\sigma}$ are stable and the leptonic decay constant decreases with increasing temperature and vanishes approximately at temperature $T = 160$ MeV. This situation may be interpreted as a signal for deconfinement and agrees with heavy-light meson investigations [28]. Numerical analysis shows that the temperature dependence of $\Delta \lambda_{\sigma}$ is the same, when $M^2$ changes between 0.9 GeV$^2$ and 1.4 GeV$^2$. Obtained results can be used in the interpretation of heavy-ion collision results. Observation of zero value of the leptonic decay constant can be considered as a signal of phase transition from hadrons to the quark–gluon plasma. We believe these studies would be of great importance for understanding phenomenological and theoretical aspects of thermal QCD.
